

A brief explanation of the code,

Our code is a program that prompts the user to ask recipe names and the ingredients, calories and servings of that recipe. It then prints the inputted values to the screen for the user to see what he entered

Our code has two classes in two files. One class is the steppingstone recipe class where we create all our attributes and methods, and the other class is the steppingstone recipe test class where we test all the methods created in the steppingstone recipe class.

Purpose of the code

The code is a recipe app that gets information from the user about a recipe such as the recipe ingredient, their calories, and the total servings in the recipe. It then prints that information back to the user.

Experience in developing it, including any issues that I encountered while completing the steppingstone

This steppingstone was incredibly challenging as I had to take a long time to understand the code. Also, the recipe test class was not working, and I had to take a long time to try to make it work.

what approaches you took to solve them

To solve both classes I just did some research and tried to understand the code. Once I understood the code it was easy to complete the started code and get the code to work properly.
